

## FAST METHOD FOR THE FORWARD AND INVERSE MDCT IN AUDIO CODING

## CROSS-REFERENCE TO RELATED APPLICATIONS

This patent application claims the benefit of the filing date of United States Provisional Patent Application Serial Nos. 60/181,271, filed February 9, 2000 and entitled "Fast Method for the Forward and Inverse MDCT in Audio Coding"; and 60/184,685, filed February 24, 2000 and entitled "Fast Method for the Forward and Inverse MDCT in Audio Coding", the entire contents of which are hereby expressly incorporated by reference.

## 10 FIELD OF THE INVENTION

The present invention relates to audio and image data compression and decompression applications. More specifically, the invention relates to a system and method for fast computation of modified discrete cosine transform (MDCT) and its inverse modified discrete cosine transform (IMDCT).

## 15 BACKGROUND OF THE INVENTION

Discrete cosine transform (DCT) is used extensively in data compression for image and speech signals. For example, the authors in N. Amed, T. Natarajan, and K. R. Rao, "Discrete Cosine Transform," *IEEE Trans. Commun.*, vol. COM-23, pp. 90-93, Jan. 1974 [1]; and Man IK Chao and Sang UK Lee, "DCT methods for VLSI parallel Implementations," *IEEE Trans. On Acoustics, Speech and Signal Processing*, vol. 38, no. 1, pp. 121-127, January 1990 [2], the contents of which are hereby incorporated by reference, describe DCT methods for data compression. Many methods have been proposed to compute the DCT. For example, see Nam IR Cho and Sang UK Lee, "DCT Methods for VLSI Parallel Implementations," *IEEE Transactions on Acoustics, Speech and Signal Processing*, vol.38, no.1, pp.121-127, January 1990 [11]; and T. K. Truong, I. S. Reed, I. S. Hsu, H. C. Shyu, and H. M. Sho, "A Pipelined Design of a Fast Prime Factor DFT on a Finite Field," *IEEE Trans. Computers*, vol. 37, pp. 266-273, Mar. 1988 [12], the contents of which are hereby incorporated by reference.

**Express Mail No. EL483171505US**

Recently, Kek in C. W. Kok, "Fast Method for Computing Discrete Cosine Transform," *IEEE Trans. on Signal Processing*, vol. 45, no. 3, pp. 757-760, March 1997 [3], the contents of which are hereby incorporated by reference, suggested a new DCT method for computing the DCT of length  $N = N_1 \times N_2$ , where  $N_1$  is an even number and  $N_2$  is an odd number. In this method, the DCT with even length  $N$  is decomposed into two DCT's with length  $N/2$ . If  $N/2$  is an odd number.

Further, it follows from Michael T. Heideman, "Computation of an Odd Length DCT from a Real-Value DFT of the Same Length," *IEEE trans. on Signal Processing*, vol. 40, no. 1, pp. 54-61, January 1992 [4], the contents of which are hereby incorporated by reference, that such a DCT of length  $N/2$  can be computed by the use of the identical length discrete Fourier transform (DFT) method developed by Winograd. This method is described in Dean P. Kolba and Thomas W. Parks, "A Prime Factor FFT Method Using High-Speed Convolution," *IEEE Trans on Acoustics, Speech and Signal processing*, vol. ASSP-25, no. 4, pp. 281-294, August 1977 [5]; and S. Winograd, "On Computing the Discrete Fourier Transform," *Mathematics of Computation*, vol. 32, no. 141, pp. 175-199, January 1978. [6], the contents of which are hereby incorporated by reference.

By using the ideas in [3, and 4], a fast method can be developed to compute an 18-point DCT. In other words, the standard 18-point DCT is decomposed first into two 9-point DCT. Then, such a 9-point DCT can be implemented by Winograd's DFT method. However, computing the MDCT and its IMDCT of an even length sequence can involve an extensive computation.

Therefore, there is a need for a fast method to compute either the MDCT or IMDCT so that it can be implemented easily on either a processor, such as a digital signal processor (DSP) or computer. Most recently, the author in K. Konstantinides, "Fast Subband Filtering in MPEG Audio Coding," *IEEE Signal Processing Letters*, vol. 1, no. 2, pp. 26-28, Feb. 1994 [7], the contents of which are hereby incorporated by reference, suggested that the MDCT and IMDCT in MPEG audio coding can be converted first into the standard DCT and IDCT, respectively. Such a DCT or IDCT can be computed rapidly by the use of Lee's fast method in Byeong Gi Lee, "A New Method to Compute the Discrete Cosine Transform,"

*IEEE Trans on Acoustics, Speech and Signal processing*, vol. ASSP-32, no. 6, pp. 1243-1245, Dec. 1984 [8], the contents of which are hereby incorporated by reference.

#### SUMMARY OF THE INVENTION

5 The modified discrete cosine transform (MDCT) and its inverse modified discrete cosine transform (IMDCT) can involve an extensive computation, for example, in layer III of the MPEG audio coding standard. The present invention computes an 18-point DCT in a fast and efficient manner. Furthermore, using this 18-point DCT method, two new methods are developed to compute the MDCT and its IMDCT, respectively. The number of  
10 multiplications and additions needed to implement both of these two new methods are reduced substantially.

In one aspect, the invention describes a method performed by a computer for computing modified discrete cosine transfer comprising the steps of:

computing 
$$x(k) = \begin{cases} [-y(26-k) - y(27+k)] \cdot b_k & \text{for } 0 \leq k \leq 8 \\ [y(k-9) - y(26-k)] \cdot b_k & \text{for } 9 \leq k \leq 17 \end{cases} ;$$

15 computing 
$$Y'(n) = \sum_{k=0}^{17} x(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \text{ for } 0 \leq n \leq 17 ;$$

defining  $Y(0) = Y'(0)/2$  ; and computing  $Y(n) = Y'(n) - Y(n-1)$  for  $1 \leq n \leq 17$  .

In another aspect, the invention describes an MPEG encoder/decoder comprising:

means for computing 
$$x(k) = \begin{cases} [-y(26-k) - y(27+k)] \cdot b_k & \text{for } 0 \leq k \leq 8 \\ [y(k-9) - y(26-k)] \cdot b_k & \text{for } 9 \leq k \leq 17 \end{cases} ;$$

means for computing 
$$Y'(n) = \sum_{k=0}^{17} x(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \text{ for } 0 \leq n \leq 17 ;$$

20 means for defining  $Y(0) = Y'(0)/2$  ; and means for computing  $Y(n) = Y'(n) - Y(n-1)$  for  $1 \leq n \leq 17$  .

The encoder/decoder may also comprise of: means for computing  $Y'(k) = Y(k) \cdot b_k$  for  $0 \leq k \leq 17$  ;

means for computing  $y'''(n) = \sum_{k=0}^{17} Y'(k) \cos[\frac{\pi}{2 \cdot 18} (2k+1)n]$  for  $0 \leq n \leq 17$  ;

means for computing  $y'(n) = \begin{cases} y'''(n+9) & \text{for } 0 \leq n \leq 8 \\ 0 & \text{for } n = 9 \\ -y'''(27-n) & \text{for } 10 \leq n \leq 26 \\ -y'''(n-27) & \text{for } 27 \leq n \leq 35 \end{cases} ;$

5 means for defining  $y(0) = \sum_{k=0}^{18-1} Y(k) \cdot c_k$  ; and means for computing  $y(n) = y'(n) - y(n-1)$  for  $1 \leq n \leq 35$  .

## BRIEF DESCRIPTION OF THE DRAWINGS

The objects, advantages and features of this invention will become more apparent from a consideration of the following detailed description and the drawings, in which:

FIG. 1 is an exemplary hardware butterfly diagram for a fast 18-18 DCT method;

FIG. 2 is an exemplary hardware butterfly diagram for a fast 36-18 MDCT method; and

FIG. 3 is an exemplary hardware butterfly diagram for fast 18-36 IMDCT described.

## DETAILED DESCRIPTION

The system and method of the present invention computes the MDCT and its IMDCT, respectively with a substantially reduced number of multiplications and additions. Additionally, a computer simulation shows that the speed of these two new methods for computing the MDCT and IMDCT are 7.2 times and 4.3 times faster than the direct methods, respectively. The present invention significantly improves the performance and effectiveness of data compression methods such as, MP III, MPEG, and other audio/video compression methods. By this means, the MDCT or IMDCT defined in Hwang-Cheng

Chiang and Jie-Cherng Liu, "Regressive Implementation for the Forward and Inverse MDCT in MPEG Audio Coding, " *IEEE Signal Processing Letters*, vol.3, no.4, pp.116-117, April 1996 [10], the contents of which are hereby incorporated by reference, can be converted first into the standard DCT of length  $N = 18$ . Then such an 18-point DCT can be implemented by using the same length Winograd's DFT method.

The advantage of this new method over the previous methods is that the 18-point DCT can be used to compute both the MDCT and IMDCT simultaneously. As a consequence, the computation of the 18-point IDCT needed to perform the MDCT method developed in Hsieh S. Hou, "A Fast Recursive Method for Computing the Discrete Cosine Transform," *IEEE Trans on Acoustics, Speech and Signal processing*, vol. ASSP-35, no. 10, pp. 1455-1461, Oct. 1987 [9], the contents of which are hereby incorporated by reference, is completely avoided in this new MDCT method. With these new techniques, the new MDCT and IMDCT methods require only a small fraction of the number of multiplications and additions that are required in direct methods, respectively.

#### Fast Method for Computing the 18-point DCT

Let  $x(k)$  be a sequence with length  $N = 18$ . The DCT of  $x(k)$  defined in [3] is given by

$$X(n) = \sum_{k=0}^{18-1} x(k) \cos \frac{\pi}{36} (2k+1)n \quad \text{for } 0 \leq n \leq 17 \quad (1)$$

In (1),  $X(n)$  can be decomposed into the even and odd indexed output of the DCT. That is,

$$A(n) = X(2n) \quad \text{for } 0 \leq n \leq 8 \quad (2)$$

$$B(n) = X(2n+1) \quad \text{for } 0 \leq n \leq 8 \quad (3)$$

By [3], (2) and (3) can be shown to be two DCT's with length 9 as fellows:

$$A(n) = \sum_{k=0}^{9-1} a(k) \cos \left[ \frac{\pi}{2 \times 9} (2k+1)n \right] \quad \text{for } 0 \leq n \leq 8 \quad (4)$$

where

$$a(k) = x(k) + x(18 - 1 - k) \quad (5)$$

and

$$B'(n) = \sum_{k=0}^{9-1} b(k) \cos\left[\frac{\pi}{2 \times 9}(2k+1)n\right] \quad \text{for } 0 \leq n \leq 8 \quad (6)$$

where

$$b(k) = 2[x(k) - x(18 - 1 - k)] \cos\left[\frac{\pi}{2 \times 18}(2k+1)\right] \quad (7)$$

$$B'(n) = B(n) + B(n-1) \quad \text{for } 0 \leq n \leq 8 \quad (8)$$

Note that  $B(0) = B(-1)$ . From (8), one obtains

$$B(0) = \frac{B'(0)}{2} \quad (9)$$

Using the sequence  $B'(n)$  obtained by (6),  $B(n)$  for  $0 \leq n \leq 8$  can be obtained by the use of both (9) and the recursive form in (8).

Since  $A(n)$  in (4) is a 9-point DCT, then, it is shown in [5] that this DCT can be computed by the use of the identical-length DFT method developed by Winograd [5,6]. To illustrate this, first, the decomposition of (4) into two even and odd values of  $n$  of the DCT appears as follows:

$$A(2n) = \sum_{k=0}^{9-1} a(k) \cos\left[\frac{\pi}{2 \times 9}(2k+1)2n\right] \quad \text{for } 0 \leq n \leq 4 \quad (10)$$

and

$$A(9-2n) = \sum_{k=0}^{9-1} a(k) \cos\left[\frac{\pi}{2 \times 9}(2k+1)(9-2n)\right] \quad \text{for } 0 \leq n \leq 4 \quad (11)$$

It follows from [4] that (10) and (11) can be shown to the following:

$$A(2n) = (-1)^n \operatorname{Re} \left\{ \sum_{k=0}^{9-1} a'(k) \omega^{nk} \right\} \quad (12)$$

and

$$A(9-2n) = (-1)^{n+1} \operatorname{Im} \left\{ \sum_{k=0}^{9-1} a'(k) \omega^{nk} \right\} \quad (13)$$

where  $\omega = e^{\frac{j2\pi}{9}}$  is the 9<sup>th</sup> root of unity and  $a'(k)$  is defined by

$$a'(k) = \begin{cases} a((-1)^{k+6}k + 4) & \text{for } 0 \leq k \leq 4 \\ a((-1)^{k+6}(9-k) + 4) & \text{for } 5 \leq k \leq 8 \end{cases} \quad (14)$$

$$(15)$$

Define the 9-point DFT as follows:

$$A'(n) = \sum_{k=0}^{9-1} a'(k) \omega^{nk} \quad (16)$$

5 It is shown in [4] that the transform in (16) can be computed with a minimum number of operations by Winograd's method. The substitution of (16) into (14) and (13) yields

$$A(2n) = (-1)^n \operatorname{Re} \{A'(n)\} \quad \text{for } 0 \leq n \leq 4 \quad (17)$$

$$A(9-2n) = (-1)^{n+1} \operatorname{Im} \{A'(n)\} \quad \text{for } 5 \leq n \leq 8 \quad (18)$$

where  $A'(n)$  is given in (16).

The detailed method given in [5] for computing the 9-point DCT in (4) is given in Appendix A. One observes from this method that the number of multiplications and  
 10 additions are 10 and 34, respectively. In a similar fashion, by replacing  $a(k)$  and  $A(n)$  by  $b(k)$  and  $B'(n)$  respectively, (6) can also be computed by the use of the method given in Appendix A.

Let  $x(k)$  be a sequence of length 18. The fast method for computing the 18-point DCT defined in (1) comprises the following three steps:

- (1). Compute  $a(k)$  and  $b(k)$  from (5) and (7). That is,

$$a(k) = x(k) + x(18-1-k) \quad \text{for } 0 \leq k \leq 8$$

$$b(k) = 2(x(k) - x(18-1-k)) \cos\left[\frac{\pi}{36}(2k+1)\right] \quad \text{for } 0 \leq k \leq 8.$$

- (2). Use the fast method given in Appendix A to compute the 9-point DCT of  $a(k)$ , i.e.

$$A(n) \text{ in (4) and the 9-point DCT of } b(k), \text{ i.e., } B'(n) \text{ in (6) for } 0 \leq n \leq 8.$$

- (3). Use both the recursive formulae for  $1 \leq n \leq 8$  in (8) and (9) to compute  $B(n)$  from

$$\text{the known } B'(n) \text{ for } 0 \leq n \leq 8. \text{ That is, } B(0) = B'(0)/2, \text{ and}$$

$$B(n) = B'(n) - B(n-1) \text{ for } 1 \leq n \leq 8. \text{ Then set } X(2n) = A(n), \text{ for } 0 \leq n \leq 8 \text{ And}$$

$$X(2n+1) = B(n) \text{ for } 0 \leq n \leq 8, \text{ where } X(n) \text{ is a 18-point DCT of } x(k) \text{ given in (1).}$$

From the method described above, it can be shown that the total number of multiplications and additions needed to compute (1) are 29 and 97, respectively. In contrast, 324 multiplications and 306 additions are required for a direct computation of (1). An exemplary butterfly diagram of a fast 18-18 DCT is depicted in FIG. 1. FIG. 1 shows an exemplary hardware butterfly diagram for the fast 18-18 DCT method. The button diagrams indicate the computation flows. The pre-computed constants are

$$d_k = 2 \cos\left[\frac{\pi}{36}(2k+1)\right] \text{ for } 0 \leq k \leq 8.$$

Fast method for Computing the MDCT

Let  $y(k)$  be a sequence of length  $N = 36$ , the MDCT of  $y(k)$  defined in [10] is given by

$$Y(n) = \sum_{k=0}^{36-1} y(k) \cos\left[\frac{\pi}{2 \cdot 36}(2k+1+18)(2n+1)\right] \quad \text{for } 0 \leq n \leq 17 \quad (19)$$

Instead of computing (19), an alternating technique is employed. To see this, replacing  $k$  by  $36-1-k$  in (19), one obtains

$$Y(n) = \sum_{k=0}^{35} y(36-1-k) \cos\left[\frac{\pi}{2 \cdot 36}((2 \cdot 36)(2n+1) - (2k+1-18)(2n+1))\right] \quad (20)$$

5 But

$$\cos\left[\frac{\pi}{2 \cdot 36}((2 \cdot 36)(2n+1) - (2k+1-18)(2n+1))\right] = -\cos\left[\frac{\pi}{2 \cdot 36}(2k+1-18)(2n+1)\right]$$

Thus, (19) becomes

$$Y(n) = -\sum_{k=0}^{35} y(36-1-k) \cos\left[\frac{\pi}{2 \cdot 36}(2k+1-18)(2n+1)\right] \quad \text{for } 0 \leq n \leq 17 \quad (21)$$

If

$$Y'(n) = Y(n) + Y(n-1) \quad \text{for } 0 \leq n \leq 17 \quad (22)$$

then

$$Y'(n) = \sum_{k=0}^{35} y'(k) \cos\left[\frac{\pi}{2 \cdot 36}(2k+1-18)(2n)\right] \quad (23a)$$

10 where

$$y'(k) = -2y(36-1-k) \cos\left[\frac{\pi}{2 \cdot 36}(2k+1-18)\right] \quad \text{for } 0 \leq k \leq 35 \quad (23b)$$

The substitution of (21) into (22) yields,

$$\begin{aligned}
 Y'(n) &= -\sum_{k=0}^{36-1} y(36-1-k) \cos\left[\frac{\pi}{2*36} (2k+1-18)(2n+1)\right] \\
 &\quad - \sum_{k=0}^{36-1} y(36-1-k) \cos\left[\frac{\pi}{2*36} (2k+1-18)(2n-1)\right] \\
 &= -\sum_{k=0}^{35} y(36-1-k) \cos\left[\frac{\pi}{2*36} ((2k+1-18)(2n)+(2k+1-18))\right] \\
 &\quad - \sum_{k=0}^{35} y(36-1-k) \cos\left[\frac{\pi}{2*36} ((2k+1-18)(2n)-(2k+1-18))\right]
 \end{aligned} \tag{24}$$

(24) can be shown as

$$\begin{aligned}
 Y'(n) &= -\sum_{k=0}^{35} 2y(36-1-k) \cos\left[\frac{\pi}{2*36} (2k+1-18)\right] \cos\left[\frac{\pi}{2*36} (2k+1-18)(2n)\right] \\
 &= \sum_{k=0}^{35} y'(k) \cos\left[\frac{\pi}{36} (2k+1-18)n\right]
 \end{aligned} \tag{25}$$

where  $y'(k)$  is given in (23b).

5 From (21), one observes that  $Y(0) = Y(-1)$ . Using this result and the recursive formula in (22), one yields

$$Y(0) = Y'(0)/2 \tag{26a}$$

$$Y(n) = Y'(n) - Y(n-1) \quad \text{for } 1 \leq n \leq 17 \tag{26b}$$

Using the sequence  $y'(n)$  obtained by (25b), the sequence  $y(n)$  for  $0 \leq n \leq 17$  can be obtained by the use of (26a) and (26b).

Let

$$y''(k) = \begin{cases} y'(k+9) & \text{for } 0 \leq k \leq 26 \\ y'(k-27) & \text{for } 27 \leq k \leq 35 \end{cases} \quad (27a)$$

$$(27b)$$

Then

$$Y'(n) = \sum_{k=0}^{35} y''(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \quad (28)$$

The proof of this is similar to that used in Lemma 1 in [7]. To prove this, (25) can be rewritten as:

$$Y'(n) = \sum_{k=0}^8 y'(k) \cos\left[\frac{\pi}{36}(2k+1-18)n\right] + \sum_{k=9}^{35} y'(k) \cos\left[\frac{\pi}{36}(2k+1-18)n\right] \quad (29)$$

Let  $k = k' + 9$ , (29) becomes

$$Y'(n) = \sum_{k'=-9}^{-1} y'(k'+9) \cos\left[\frac{\pi}{36}(2k'+1)n\right] + \sum_{k'=0}^{26} y'(k'+9) \cos\left[\frac{\pi}{36}(2k'+1)n\right] \quad (30)$$

5 Also, let  $k' + 9 = k - 27$  in the first summation and let  $k' = k$  in the second summation of (30).

Then

$$Y'(n) = \sum_{k=27}^{35} y'(k-27) \cos\left[\frac{\pi}{36}((2k+1)n - (2 \times 36)n)\right] + \sum_{k=0}^{26} y'(k+9) \cos\left[\frac{\pi}{36}(2k+1)n\right] \quad (31)$$

But

$$\cos\left[\frac{\pi}{36}((2k+1)n - (2 \times 36)n)\right] = \cos\left[\frac{\pi}{36}(2k+1)n\right]$$

Thus, (31) becomes

$$Y'(n) = \sum_{k=0}^{35} y''(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \quad (32)$$

where  $y''(k)$  is given in (27a) and (27b).

10 For given  $y''(k)$  as defined in (27a) and (27b),

$$X(n) = Y'(n) = \sum_{k=0}^{17} x(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \quad \text{for } 0 \leq n \leq 17 \quad (33)$$

where

$$x(k) = y''(k) + y''(36-1-k) \quad \text{for } 0 \leq k \leq 17 \quad (34)$$

The proof of this is also similar to that used in Lemma 2 in [7]. To see this, (32) can be rewritten as

$$Y'(n) = Y_1'(n) + Y_2'(n) \quad \text{for } 0 \leq n \leq 35 \quad (35)$$

where

$$Y_1'(n) = \sum_{k=0}^{17} y''(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \quad (36)$$

5 and

$$Y_2'(n) = \sum_{k=18}^{35} y''(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \quad (37)$$

Let  $k = 36-1-k'$ . Then  $Y_2'(n)$  in (37) becomes

$$Y_2'(n) = \sum_{k'=17}^0 y''(36-1-k') \cos\left[\frac{\pi}{36}(2(36-1-k')+1)n\right] \quad (38)$$

However,

$$\cos\frac{\pi}{36}(2 \times 36n - (2k'+1)n) = \cos\frac{\pi}{36}(2k'+1)n$$

Hence, let  $k' = k$ , (38) becomes

$$Y_2'(n) = \sum_{k'=0}^{17} y''(36-1-k') \cos\frac{\pi}{36}(2k'+1)n \quad (39)$$

The substitution (39) and (36) into (35) yields

$$\begin{aligned}
y'(n) &= \sum_{k=0}^{17} y''(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] + \sum_{k=0}^{17} y''(36-1-k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \\
&= \sum_{k=0}^{17} x(k) \cos\left[\frac{\pi}{36}(2k+1)n\right] \quad \text{for } 0 \leq n \leq 17
\end{aligned} \tag{40}$$

where  $x(k)$  is given in (33). From the above, it can be seen that (33) is an 18-point DCT which can be efficiently computed by the use of the fast method given in the previous section.

Suppose that  $y(k)$  is a sequence of length  $N=36$ . For  $0 \leq k \leq 8$ , one has

5  $27 \leq 36-1-k \leq 35$ . Thus, from (27) and (23b), (34) becomes

$$\begin{aligned}
x(k) &= y''(k) + y''(36-1-k) \\
&= y'(k+9) + y'(8-k) \\
&= -2y(26-k) \cos\left[\frac{\pi}{2 \times 36}(2k+1)\right] - 2y(27+k) \cos\left[\frac{\pi}{2 \times 36}(2k+1)\right] \\
&= [-y(26-k) - y(27+k)] \cdot 2 \cos\left[\frac{\pi}{2 \times 36}(2k+1)\right]
\end{aligned}$$

Similar, for  $9 \leq k \leq 17$ , (34) becomes

$$\begin{aligned}
x(k) &= y'(k+9) + y'(44-k) \\
&= -2y(26-k) \cos\left[\frac{\pi}{2 \times 36}(2k+1)\right] - 2y(k-9) \cos\left[\frac{\pi}{2 \times 36}(71-2k)\right] \\
&= [y(k-9) - y(26-k)] \cdot 2 \cos\left[\frac{\pi}{72}(2k+1)\right]
\end{aligned}$$

since  $\cos\left[\frac{\pi}{2 \times 36}(71-2k)\right] = -\cos\left[\frac{\pi}{2 \times 36}(2k+1)\right]$ .

Let  $b_k = 2 \cos\left[\frac{\pi}{2 \times 36}(2k+1)\right]$  be the pre-computed constants. The fast method for

computing the MDCT of  $y(k)$  in (19) is composed of the following three successive steps of

computation:

(1). Compute

$$x(k) = \begin{cases} [-y(26-k) - y(27+k)] \cdot b_k & \text{for } 0 \leq k \leq 8 \\ [y(k-9) - y(26-k)] \cdot b_k & \text{for } 9 \leq k \leq 17 \end{cases}$$

(2). Use the fast method described in Section II to compute the 18-point DCT of  $x(k)$ ,

5 i.e.,  $Y'(n)$  defined in (40). That is,  $Y'(n) = \sum_{k=0}^{17} x(k) \cos[\frac{\pi}{36}(2k+1)n]$  for

$$0 \leq n \leq 17$$

(3). Let  $Y(0) = Y'(0)/2$ .

Then compute  $Y(n) = Y'(n) - Y(n-1)$  for  $1 \leq n \leq 17$ .

10 This new method is simpler and faster than that of the brute-force method. The number of multiplications and additions needed for this method and the brute-force method is given in Table 1. Table 1 shows that the multiplications and additions needed to implement this new method require only 10.03% and 20.95% of the brute-force method, respectively. The butterfly diagram of the fast 36-18 MDCT is depicted in FIG. 2. FIG. 2 illustrates an  
15 exemplary hardware butterfly diagram for the above fast 36-18 MDCT method. The butterfly diagram indicates the computation flow. The pre-computed constants are

$$b_k = 2 \cos[\frac{\pi}{2 \times 36}(2k+1)].$$

#### Fast Method for Computing the IMDCT

Let  $Y(k)$  for  $0 \leq k \leq 17$  be the output sequence of (19). The inverse MDCT of  $Y(k)$

defined in [10] is given by

$$y(n) = \sum_{k=0}^{18-1} Y(k) \cos\left[\frac{\pi}{2 * 36} (2n+1+18)(2k+1)\right] \quad \text{for } 0 \leq n \leq 35 \quad (41)$$

If  $y'(n) = y(n) + y(n-1)$ , using a proof similar to that used in (24)-(26), then (41) can be expressed by

$$y'(n) = \sum_{k=0}^{18-1} Y'(k) \cos\left[\frac{\pi}{2 * 36} (2n+18)(2k+1)\right] \quad \text{for } 0 \leq n \leq 35 \quad (42)$$

where

$$Y'(k) = 2Y(k) \cos\left[\frac{\pi}{2 * 36} (2k+1)\right] \quad \text{for } 0 \leq k \leq 17 \quad (43)$$

5 It follows from (41) that

$$y(0) = \sum_{k=0}^{18-1} Y(k) \cos\left[\frac{\pi}{2 * 36} (19)(2k+1)\right] \quad (44)$$

Using the sequence  $y'(n)$  obtained by (42), again,  $y(n)$  can be obtained by the use of the initial condition  $y(0)$  given in (44) and the recursive formula  $y(n) = y'(n) - y(n-1)$  for  $1 \leq n \leq 35$ .

Define

$$y''(n) = \begin{cases} y'(n-9) & \text{for } 9 \leq n \leq 35 \\ y'(n+27) & \text{for } 0 \leq n \leq 8 \end{cases} \quad (45)$$

$$(46)$$

10 From (42), (45) and (46) can be shown to the following

$$y''(n) = y'(n-9) = \sum_{k=0}^{18-1} Y'(k) \cos\left[\frac{\pi}{2 * 36} (2k+1)2n\right] \quad \text{for } 9 \leq n \leq 35 \quad (47)$$

$$y''(n) = y'(n+27) = \sum_{k=0}^{18-1} Y'(k) \cos\left[\frac{\pi}{2*36}(2n+72)(2k+1)\right] \quad \text{for } 0 \leq n \leq 8 \quad (48)$$

In (47), it is can be shown that  $y''(18) = 0$ . Based on [7], the following can be proved:

In (47) and (48),

$$y''(18+j) = -y''(18-j) \quad \text{for } 1 \leq j \leq 9 \quad (49)$$

$$y''(18+j) = y''(18-j) \quad \text{for } 10 \leq j \leq 17 \quad (50)$$

Thus, for  $1 \leq j \leq 9$ , from (47), one has

$$\begin{aligned} y''(18+j) &= \sum_{k=0}^{18-1} Y'(k) \cos\left[\frac{\pi}{2*36} \cdot 2(18+j)(2k+1)\right] \\ &= \sum_{k=0}^{18-1} Y'(k) \cos\left[\frac{\pi}{2*36} (2*18)(2k+1) + \frac{\pi}{4*18} (2j)(2k+1)\right] \end{aligned} \quad (51)$$

5 Using  $\cos(A+B) = \cos A \cdot \cos B - \sin A \cdot \sin B$ , (51) becomes

$$y''(18+j) = -\sum_{k=0}^{18-1} Y'(k) \sin\left[\frac{\pi}{2} (2k+1)\right] \cdot \sin\left[\frac{\pi j}{2*18} (2k+1)\right] \quad \text{for } 1 \leq j \leq 9 \quad (52)$$

Similarly,

$$\begin{aligned} y''(18-j) &= \sum_{k=0}^{18-1} Y'(k) \cos\left[\frac{\pi}{4*18} 2(18-j)(2k+1)\right] \\ &= \sum_{k=0}^{18-1} Y'(k) \sin\left[\frac{\pi}{2} (2k+1)\right] \cdot \sin\left[\frac{\pi j}{2*18} (2k+1)\right] \quad \text{for } 1 \leq j \leq 9 \end{aligned} \quad (53)$$

From (52) and (53),  $y''(18+j) = -y''(18-j)$  for  $1 \leq j \leq 9$ .

For  $10 \leq j \leq 17$ , from (48), one has

$$\begin{aligned}
y''(18-j) &= \sum_{k=0}^{17} Y'(k) \cos\left[\frac{\pi}{2*36}(2(18-j)+72)(2k+1)\right] \\
&= \sum_{k=0}^{17} Y'(k) \cos\left[\frac{108\pi}{2*36}(2k+1) - \frac{\pi j}{2*18}(2k+1)\right]
\end{aligned} \tag{54}$$

Again, using  $\cos(A-B) = \cos A \cdot \cos B + \sin A \cdot \sin B$ , (54) becomes

$$y''(18-j) = \sum_{k=0}^{17} Y'(k) \sin\left[\frac{3\pi}{2}(2k+1) \cdot \sin\frac{\pi j}{2*18}(2k+1)\right] \tag{55}$$

However,  $\sin\frac{3\pi}{2}(2k+1) = -\sin\frac{\pi}{2}(2k+1)$ . Hence, (55) becomes

$$y''(18-j) = -\sum_{k=0}^{17} Y'(k) \sin\left[\frac{\pi}{2}(2k+1)\right] \cdot \sin\left[\frac{\pi j}{2*18}(2k+1)\right] \tag{56}$$

From (52) and (54),  $y''(18+j) = -y''(18-j)$  for  $10 \leq j \leq 17$ .

It follows from the above proof that one only computes  $y''(n)$  for  $0 \leq n \leq 17$ . In other words, for given  $y''(n)$ , where  $0 \leq n \leq 17$ ,  $y''(n)$  for  $19 \leq n \leq 35$  can be obtained from using (49) and (50). Recall that  $y''(18) = 0$ .

Also, by defining

$$y'''(n) = -y''(n) \quad \text{for } 0 \leq j \leq 8 \tag{57}$$

$$y'''(n) = y''(n) \quad \text{for } 9 \leq j \leq 17 \tag{58}$$

Then

$$y'''(n) = \sum_{k=0}^{17} Y'(k) \cos\left[\frac{\pi}{2*18}(2k+1)n\right] \quad \text{for } 0 \leq n \leq 17 \tag{59}$$

As a result, for  $0 \leq n \leq 8$ , from (48), one yields

$$\begin{aligned}
y''(n) &= \sum_{k=0}^{17} Y'(k) \cos\left[\frac{\pi}{2 \cdot 18} n(2k+1) + \pi(2k+1)\right] \\
&= -\sum_{k=0}^{17} Y'(k) \cos\left[\frac{\pi}{2 \cdot 18} (2k+1)n\right] \\
&= -y'''(x)
\end{aligned}$$

For  $9 \leq n \leq 17$ , from (47), one obtains  $y'''(n) = y''(n)$ .

In (59),  $y'''(n)$  is an 18-point DCT. By replacing  $y'''(n)$  and  $Y'(k)$  by  $X(n)$  and  $x(k)$ , respectively, the 18-point DCT in (59) is the same as (1). As a consequence, the fast method developed in Section II can also be used to compute (59).

5 From (45) and (46), one has

$$y'(n) = \begin{cases} y''(n+9) & \text{for } 0 \leq n \leq 26 \\ y''(n-27) & \text{for } 27 \leq n \leq 35 \end{cases}$$

Together with (49), (50), (57) and (58),  $y'(n)$  can be expressed in terms of  $y'''(n)$  as follows:

$$y'(n) = y''(n+9) = y'''(n+9) \quad \text{for } 0 \leq n \leq 8$$

$$y'(n) = y''(n+9) = y''(18) = 0 \quad \text{for } n = 9$$

$$\begin{aligned}
y'(n) &= y''(n+9) \\
&= y''(18 + (n-9)) \\
&= -y''(18 - (n-9)) & \text{for } 10 \leq n \leq 18 \\
&= -y''(27-n) \\
&= -y'''(27-n)
\end{aligned}$$

$$y'(n) = -y'''(27-n) \quad \text{for } 19 \leq n \leq 26$$

$$y'(n) = -y'''(n-27) \quad \text{for } 27 \leq n \leq 35$$

Let  $Y(k)$  for  $0 \leq k \leq 17$  be the output sequence of (19). Also let  $b_k = 2 \cos[\frac{\pi}{2 \times 36}(2k+1)]$  be the pre-computed constants which are the same as those defined in the MDCT method in the previous section. Finally, let  $c_k = \cos[\frac{19\pi}{2 \times 36}(2k+1)]$ .

The fast method for computing (41) is comprised of the following 4 steps of computation:

- 5 (1). Compute

$$Y'(k) = Y(k) \cdot b_k \quad \text{for } 0 \leq k \leq 17$$

- (2). Use the fast method described in Section II to compute the 18-point DCT

of  $Y(k)$  given in (59). That is,

$$y'''(n) = \sum_{k=0}^{17} Y'(k) \cos[\frac{\pi}{2 \times 18}(2k+1)n] \quad \text{for } 0 \leq n \leq 17$$

- 10 (3). Compute

$$y'(n) = \begin{cases} y'''(n+9) & \text{for } 0 \leq n \leq 8 \\ 0 & \text{for } n = 9 \\ -y'''(27-n) & \text{for } 10 \leq n \leq 26 \\ -y'''(n-27) & \text{for } 27 \leq n \leq 35 \end{cases}$$

- (4). Let  $y(0) = \sum_{k=0}^{18-1} Y(k) \cdot c_k$ .

Then compute  $y(n) = y'(n) - y(n-1)$  for  $1 \leq n \leq 35$ .

15 It is easy to observe that this new method for computing the IMDCT is simpler and faster than that of the brute-force method. The number of multiplications and additions needed for this fast method and the brute-force method is given Table 1. Table 1 shows

that the number of multiplications and additions required to implement this new method are only 7.25% and 10.03%, respectively, of the brute-force method. The butterfly diagram of the fast 18-36 IMDCT is depicted in Figure 3.

#### Program Implementation and Simulation Results

The MDCT and its IMDCT methods described above can be computed simultaneously by using the 18-point DCT. These two new methods are implemented using C++ language run on a Pentium 133/Windows 98 platform, in which the multiplications and additions are implemented using double data type. An example of the source code is given in Appendix B. The fast methods are verified by comparing their results of  $10^6$  computations to those of the brute-force methods. The computation times are provided in Table 1, which is in millisecond averaged from  $10^6$  computations. These new methods for computing the MDCT and IMDCT require 0.0218 ms and 0.0375 ms as compared to 0.1567 ms and 0.1616 ms required by the brute-force methods, respectively.

As a consequence, the new methods for computing the MDCT and IMDCT are 7.2 and 4.3 times faster than the brute-force methods, respectively. In addition to audio compression such as MP III method, the resulting improvement is also useful for video compression methods such as MPEG method.

Additionally, the method of the present invention may be implemented in a custom application-specific integrated circuits (ASICs), general-purpose programmable DSP using firmware to program the DSP devices, and customizable arrays such as programmable logic arrays (PLAs) and field-programmable arrays (FPAs). Because the present invention uses the same encoding and decoding (recording and playback), the complexity of software, firmware, and hardware is significantly reduced resulting in cost improvement and flexibility, in addition to speed improvement.

FIG. 3 is an exemplary hardware butterfly diagram for fast 18-36 IMDCT described. The butterfly diagram indicates the computation flow. The pre-computed constants are

$$b_k = 2 \cos\left[\frac{\pi}{2 \times 36}(2k + 1)\right] \text{ and}$$

$$y(0) = \sum_{k=0}^{18-1} Y(k) \cdot c_k \text{ where } c_k = \cos\left[\frac{19\pi}{2 \times 36}(2k+1)\right].$$
